Haiti Weather Hazards and Benefits Assessment

For
June 5 – 11, 2007

The first season on Hispaniola was normal to slightly above normal. Well distributed rainfall provided plenty of moisture for crops across the island. There were isolated flooding incidents, including in Port-au-Prince. After the end of the first season, rainfall dropped significantly allowing for harvesting activities and sowing of second season crops. Since then rainfall has returned to the island and the second season has begun with normal amounts of rainfall.
