

Climate Prediction Center's Afghanistan Hazards Outlook 13 July – 19 July, 2023

Temperature:

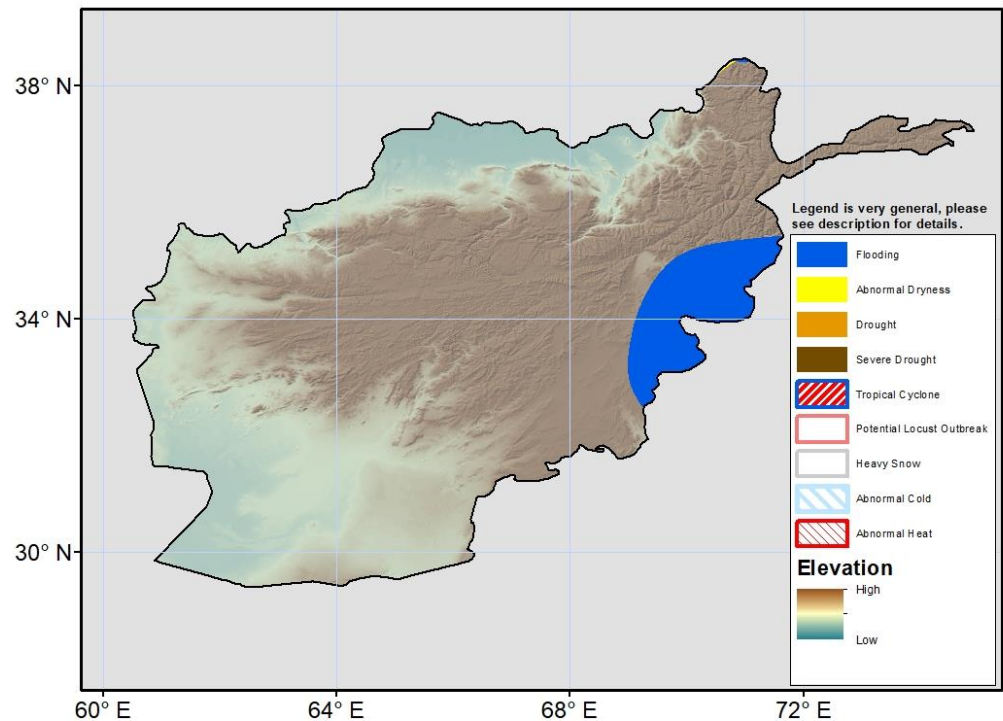

Mean maximum temperatures were below average across a few parts of northeastern Afghanistan and near average elsewhere during the past week. Maximum temperature anomalies were 2-4°C. Maximum temperature exceeded 40°C in many parts of Farah, Nimroz, Hilmand, and Kandahar during the period. Weekly minimum temperatures were 2-4°C below average in central, eastern and northeastern Afghanistan and near average elsewhere. Minimum temperatures were 5-10°C in the highest elevations and low elevations (below ~1500m) remained above 20°C.

During the outlook period, mean maximum temperatures are forecasted to be generally near to average across Afghanistan. As is typical this time of year, maximum temperatures will exceed 40°C in many of the lower elevations (below ~1500m) and likely exceed 45°C in parts of Farah and Nimroz provinces. Mean minimum temperatures are forecasted to be 1-4°C above average in the West, South, and Southeast.

Precipitation:

During the last 7 days, southeastern and eastern areas of Afghanistan received light to moderate rain. Rainfall totals of 10mm to locally 50mm were observed according to both gauges and satellite estimates. 30-day rainfall analysis shows positive anomalies of 10-100mm over southeastern and eastern zones. Longer-term deficits (10-50mm) still remain present according to 90-day analysis in northern and western areas in association with the end of the previous season. Those regions are in the midst of their dry season. Vegetation health indices show considerably degraded ground conditions in northern and western provinces because of the poor rains, but increasingly lush conditions in the East and Southeast.

For the outlook period, light to locally moderate rain are likely in eastern Afghanistan associated with the northern extent of the Indian Monsoon. Total rainfall of 10-25mm of precipitation is expected and may be enough to lead to flooding over already-wet areas. The remainder of the country is seasonably dry.

Note: The Hazards outlook map is based on current weather/climate information, short and medium-range weather forecasts (up to 1 week), sub-seasonal forecasts up to 4 weeks, and assesses the potential impact of extreme events on crop and pasture conditions. Shaded polygons are added in areas where anomalous conditions have been observed and predicted to continue during the outlook period. The boundaries of these polygons are only approximate at the spatial scale of the map. This product considers long-range seasonal climate forecasts but does not reflect current or projected food security conditions. FEWS NET is a USAID-funded activity whose purpose is to provide objective information about food security conditions. Its views are not necessarily reflective of those of USAID or the U.S. Government. The FEWS NET weather hazards outlook process and products include participation by FEWS NET field and home offices, NOAA-CPC, USGS, USDA, NASA, and several other national and regional organizations in the countries concerned.

Questions or comments about the hazard's outlooks may be directed to Dr. Wassila Thiaw, Head, International Desks/NOAA, wassila.thiaw@noaa.gov. Questions about the USAID FEWS NET activity may be directed to Dr. James Verdin, Program Manager, FEWS NET/USAID, jverdin@usaid.gov
